ManoMitra: A Safety-First Multi-Role AI-Driven Mental Health Support Platform

Varun Bantia, Prathyusha K, Venkatashiva C Reddy, Mr. Jerrin Joe Francis
Department of Computer Science and Engineering
Presidency University

***Abstract*—The rapid progress of conversational artificial intelligence has opened new possibilities for delivering accessible and scalable mental health support. Digital platforms powered by AI are increasingly being explored as supplementary tools for emotional assistance, particularly in environments where timely professional help may not always be immediately available. However, introducing AI systems into sensitive mental health contexts requires careful attention to safety, reliability, and ethical responsibility. Inappropriate or unfiltered responses in high-risk situations—such as self-harm ideation—can have serious consequences.**

To address these concerns, this paper presents *ManoMitra*, a multi-role mental health support platform designed to combine artificial intelligence with structured human oversight. The system integrates an AI-driven conversational companion with professional counseling workflows, crisis monitoring mechanisms, and anonymized institutional analytics. A key aspect of the platform is its two-layer safety architecture, in which user inputs are first evaluated through an on-device semantic safety model before being processed by a large language model. This layered design aims to prevent unsafe generative outputs while preserving conversational empathy and contextual relevance. Experimental evaluation indicates that the approach enhances response safety without compromising user engagement, demonstrating the feasibility of responsible AI deployment in digital mental health ecosystems.

I. Introduction

Conversational agents have progressed remarkably over the past several decades, moving from simple rule-based programs to sophisticated transformer-based language models capable of contextual reasoning and human-like dialogue. Early systems such as ELIZA demonstrated that even relatively basic conversational structures could create a sense of therapeutic engagement [1]. In recent years, the emergence of large-scale transformer-based language models such as GPT-3 has significantly expanded the expressive and reasoning capabilities of conversational systems [2]. These models can interpret complex linguistic patterns and generate coherent responses across diverse scenarios. However, as such systems begin to operate in sensitive domains—particularly mental health—questions surrounding reliability, safety, and ethical responsibility become increasingly critical [3].

Alongside these technological advancements, mental health–focused conversational platforms have gained attention as scalable tools for emotional support and structured therapeutic guidance. Systems such as Woebot have shown that automated conversational agents can deliver cognitive behavioral therapy (CBT)-based interventions with measurable improvements in depressive symptoms [4]. Similarly, empathy-driven digital agents have demonstrated the potential to improve emotional well-being through accessible conversational interfaces [5]. Despite these promising outcomes, many existing solutions depend heavily on scripted dialogue flows or centralized cloud moderation. This reliance can introduce latency, limit contextual adaptability, and raise concerns about data privacy. More importantly, generative AI models that lack robust safeguards may produce inappropriate or unsafe responses in situations involving self-harm ideation or crisis-related language. AI safety research emphasizes the necessity of layered protective mechanisms when intelligent systems are deployed in high-stakes environments [6], [7].

These limitations highlight the need for a hybrid architecture that combines real-time safety filtering with conversational intelligence.

Motivated by these challenges, we introduce **ManoMitra**, a comprehensive Android-based mental health support platform designed to integrate artificial intelligence with structured human oversight. Rather than functioning solely as a conversational chatbot, ManoMitra combines AI-driven dialogue assistance with professional counseling workflows, moderated peer support, crisis detection capabilities, and anonymized institutional analytics. The system operates within a clearly defined role-based ecosystem comprising Students, Counselors, and Administrators. Students can interact with a safety-aware AI companion, track mood states, schedule appointments with verified counselors, and engage in secure communication once sessions are confirmed. Counselors manage appointment workflows and crisis alerts, while administrators access aggregated mental health trends without exposure to personally identifiable information.

The central contribution of ManoMitra lies in its hybrid, safety-first architectural design. User inputs are evaluated locally through a lightweight on-device semantic risk detection model prior to any generative processing. If a message is identified as potentially harmful, the system bypasses generative processing and instead activates structured crisis support pathways. Beyond its safety architecture, the platform enforces a one-account-one-role security model, incorporates multilingual interaction across regional languages to improve accessibility, and supports anonymous login to reduce stigma and encourage early engagement. By combining AI assistance with professional care and institutional insight, ManoMitra demonstrates how digital mental health systems can be both

scalable and responsibly designed.

II. Literature Review

The development of AI-driven mental health systems spans multiple research domains, including conversational agents, large language models, suicide ideation detection, digital therapeutic interventions, and AI safety frameworks. Recent advances have focused on improving contextual understanding, emotional intelligence, and safety mechanisms in high-risk applications. This section reviews contemporary research and identifies gaps addressed by ManoMitra.

A. Conversational Agents in Therapeutic Contexts

Recent studies have demonstrated the growing effectiveness of conversational agents in delivering mental health support. Wang et al. [8] highlighted that AI-driven chatbots can assist in early detection of psychological distress through natural language interaction. Similarly, Shing et al. [9] emphasized the role of conversational AI in identifying emotional patterns and providing scalable support systems. These systems improve accessibility but often lack robust safety mechanisms for handling crisis-level inputs.

B. Transformer-Based Language Models

Large language models (LLMs) have significantly advanced conversational capabilities. Bommasani et al. [7] discussed the opportunities and risks associated with foundation models, including their ability to generate contextually rich responses. However, these models are prone to hallucinations and uncontrolled outputs, especially in sensitive domains such as mental health. Recent work by Liu et al. [12] demonstrates that integrating emotion-aware mechanisms improves contextual understanding but does not fully address safety concerns in real-time interactions.

C. Digital Mental Health Interventions

AI-driven mental health platforms have shown promise in providing scalable interventions. Wang et al. [8] demonstrated that deep learning models can effectively analyze user-generated text for mental health assessment. Pham et al. [10] further explored multimodal approaches for suicide risk detection, highlighting the importance of combining textual and contextual signals. Despite these advancements, most systems rely on cloud-based processing and lack real-time safety filtering mechanisms.

D. Suicide Ideation Detection Using Deep Learning

Recent research has focused on improving the accuracy of suicide ideation detection using deep learning techniques. Ji et al. [11] provided a comprehensive survey of machine learning approaches, emphasizing the effectiveness of neural models in capturing contextual semantics. Attention-based architectures have been shown to improve detection performance by focusing on emotionally significant tokens [12]. However, most studies evaluate models in offline settings, limiting their applicability in real-time conversational environments.

E. AI Safety and Secure Deployment

AI safety has emerged as a critical area of research, particularly for high-risk applications. Bommasani et al. [7] emphasized the need for structured safety mechanisms in foundation models. Privacy-preserving techniques and secure deployment strategies are also essential for handling sensitive user data in healthcare systems [21]. However, the integration of real-time safety filtering within conversational pipelines remains an open challenge.

F. Research Gap

Despite significant advancements, existing systems exhibit several limitations:

1) Conversational agents lack robust real-time safety filtering mechanisms.
2) Suicide detection models are primarily evaluated in offline settings.
3) Generative AI systems lack pre-generation safety gating.
4) Many solutions rely on cloud-based processing, raising privacy concerns.

ManoMitra addresses these limitations by integrating:

- On-device semantic suicide risk detection using a BiLSTM-attention architecture.
- A lightweight neural classifier optimized for mobile deployment.
- A strict pre-generation safety gating mechanism for LLM interaction.
- Structured crisis intervention pathways.
- A multi-role ecosystem combining AI assistance with professional oversight.

By combining advances in deep learning, AI safety frameworks, and mobile deployment optimization, the proposed system contributes toward the development of responsible and scalable digital mental health platforms.

III. Hybrid Safety Model Architecture

A. Design Motivation

Deploying conversational AI in mental health applications requires stringent safety mechanisms to prevent harmful or inappropriate responses, particularly in high-risk scenarios such as self-harm ideation. Purely generative models may produce unsafe outputs if not properly constrained. Therefore, a pre-generation safety layer is essential to filter and assess user input before it reaches the conversational model. AI safety research highlights the importance of layered defense mechanisms in high-risk systems [6], [7].

To address these challenges, ManoMitra adopts a hybrid safety-first architecture in which all user inputs are evaluated using an on-device risk detection model prior to any large language model (LLM) interaction. This approach ensures that potentially harmful inputs are intercepted early and redirected to structured crisis intervention pathways.

Unlike traditional server-side moderation systems, the proposed design emphasizes low-latency, privacy-preserving, and real-time safety evaluation directly on the user device.

B. Model Architecture

The safety model follows a two-stage hybrid architecture combining semantic understanding with deterministic safeguards, as illustrated in Fig. 1:

1) **Semantic Risk Detection:** A neural network-based classifier analyzes the contextual meaning of user input to estimate suicide risk probability.Deep learning approaches have demonstrated strong performance in suicide ideation detection tasks, particularly when contextual modeling is incorporated [11], [12].
2) **Keyword-Based Reinforcement:** A rule-based keyword scoring mechanism operates in parallel to capture explicit risk indicators, improving robustness against semantic ambiguity.

1) Text Representation: Input text is first preprocessed through normalization steps including lowercasing, removal of special characters, and tokenization. The processed text is then converted into dense vector representations using an embedding layer. Distributed word representations enable semantic understanding of textual inputs [13].

Let:

$$X = \{x_1, x_2, ..., x_n\}$$

represent the input token sequence, where each token is mapped to a fixed-dimensional embedding vector.

2) Contextual Sequence Modeling: To capture contextual dependencies in text, a Bidirectional Long Short-Term Memory (BiLSTM) network is employed. LSTM-based architectures are widely used for sequence modeling due to their ability to capture long-term dependencies [14]. Bidirectional processing further improves contextual understanding by analyzing sequences in both forward and backward directions [15].

$$H = \text{BiLSTM}(X)$$

where H represents the contextual hidden states.

3) Attention Mechanism: A self-attention mechanism is applied to the BiLSTM outputs to identify and emphasize critical parts of the input sequence. Attention mechanisms improve performance and interpretability in text classification tasks by focusing on semantically important tokens [16], [17].

$$A = \text{Attention}(H)$$

The attention-weighted representation enhances the model's ability to detect implicit expressions of distress.

4) Risk Classification Layer: The attention output is passed through a series of fully connected layers for final classification. Deep neural networks are commonly used for classification tasks following feature extraction [18].

- Dense(64) + ReLU + Dropout(0.5)
- Dense(32) + ReLU + Dropout(0.3)
- Output(1) + Sigmoid

The output represents the probability of suicidal intent:

$$\hat{y} = \sigma(Wx + b)$$

Binary cross-entropy is used as the loss function:

$$L = -(y \log(\hat{y}) + (1 - y) \log(1 - \hat{y}))$$

Dropout regularization is applied to prevent overfitting and improve generalization [19].

C. Training Configuration

The model is implemented using TensorFlow/Keras and trained on a large-scale mental health text dataset. An 80/20 train-test split is used for evaluation.

Key training configurations include:

- Optimizer: Adam
- Learning rate: 0.001
- Early stopping based on validation loss
- Dropout regularization to prevent overfitting

The training objective prioritizes high recall for high-risk cases to ensure that no critical instances are missed, which is essential in safety-critical applications.

D. Mobile Deployment and Optimization

To enable real-time inference on mobile devices, the trained model is converted into TensorFlow Lite format. Dynamic range quantization reduces model size and improves inference efficiency while maintaining acceptable accuracy.

E. Real-Time Safety Pipeline

The on-device safety pipeline operates as follows:

1) User input is preprocessed and tokenized.
2) The BiLSTM-attention model computes semantic risk probability $P_{semantic}$.
3) A parallel keyword-based module computes $P_{keyword}$.
4) Final risk score is computed as:

$$R = \max(P_{semantic}, P_{keyword})$$

The max function ensures that explicit keyword signals are not suppressed by semantic ambiguity, improving safety robustness.

5) If $R \geq 0.5$, the system blocks LLM response generation.
6) A structured crisis intervention module is activated.
7) Otherwise, the input is forwarded to the conversational AI.

F. Fallback Safety Mechanism

To ensure robustness under failure conditions, a fallback mechanism is implemented using lightweight statistical features and keyword-based scoring.

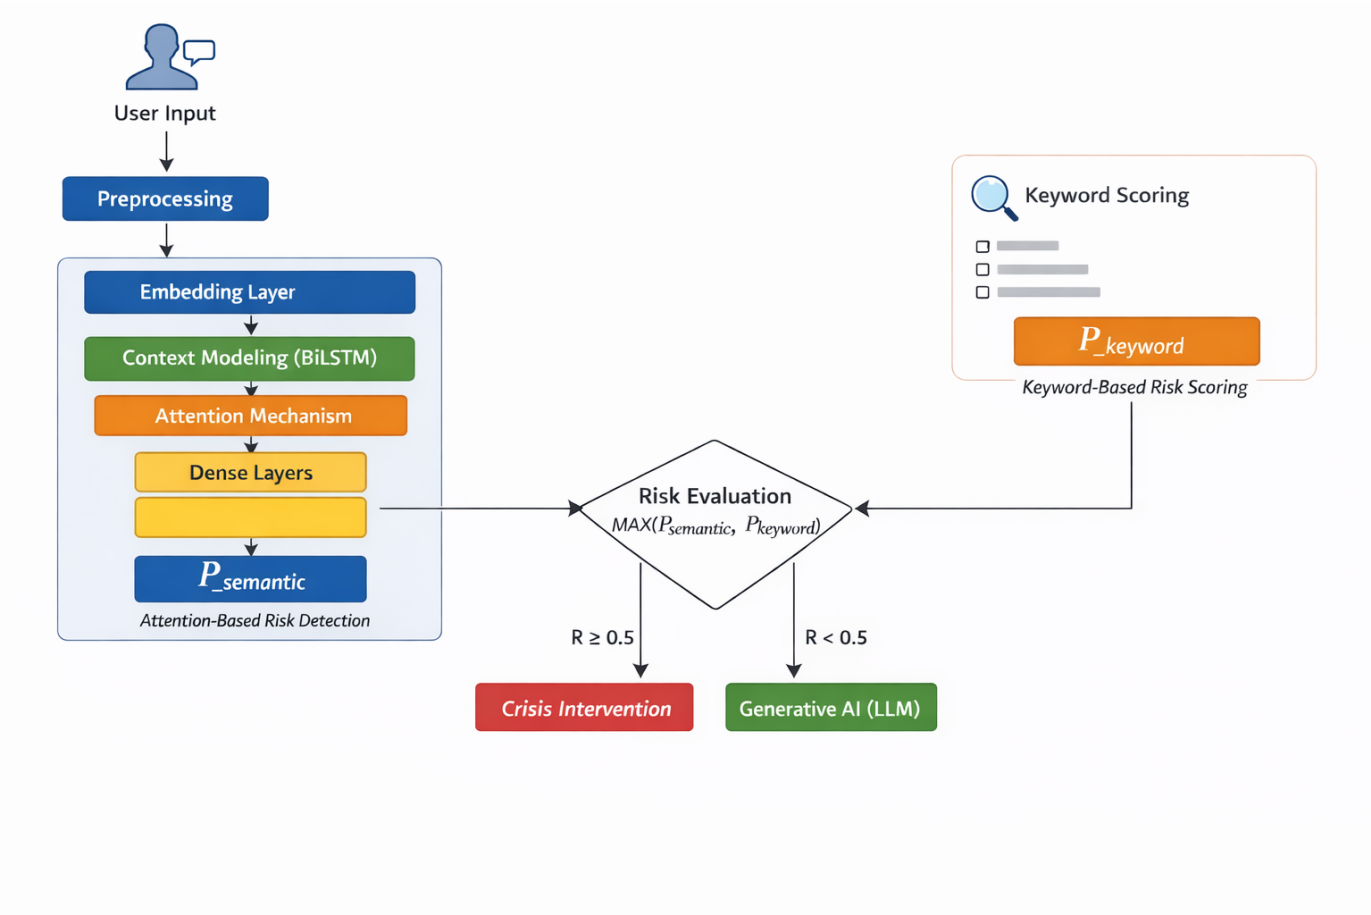

Fig. 1. Hybrid safety model architecture of ManoMitra. The system integrates a BiLSTM-attention based semantic classifier with a keyword-based risk scoring mechanism. The final risk score is computed using a max function to enable real-time safety filtering before interaction with the generative AI model.

G. Comparison with Prior Work

Existing suicide detection systems primarily operate as offline classifiers and are not integrated into real-time conversational pipelines [11]. Additionally, many conversational AI systems lack a dedicated pre-generation safety layer.

The proposed architecture differs in the following aspects:

- Real-time, on-device risk detection
- Integration of neural and rule-based safety mechanisms
- Strict pre-generation filtering before LLM interaction
- Mobile-optimized deployment with low latency

By combining contextual sequence modeling, attention-based risk detection, and deterministic safety reinforcement, the proposed system provides a practical and scalable solution for safe conversational AI deployment in mental health applications.

IV. Methodology

This section describes the complete system design and implementation framework of the proposed ManoMitra platform. The methodology integrates mobile application architecture, hybrid AI safety modeling, role-based authentication, secure communication workflows, and privacy-preserving analytics. The system is designed to ensure scalable deployment while maintaining responsible AI safeguards in mental health environments.

A. System Architecture Overview

ManoMitra follows a modular, multi-layer Android architecture consisting of:

- On-device AI Safety Layer (TensorFlow Lite)
- Cloud-based Large Language Model (LLM) API
- Firebase Authentication
- Firebase Firestore NoSQL Database
- Role-based Activity Navigation

The system is divided into three primary operational layers:

1) **Client Layer (Android Application)** – UI rendering, local inference, and role-based navigation.
2) **Intelligence Layer** – Hybrid safety model and LLM integration.
3) **Cloud Backend Layer** – Authentication, persistent storage, and analytics aggregation.

User input is processed locally through the safety layer before any interaction with the generative model, aligning with AI safety principles recommended for high-risk domains [6], [7].

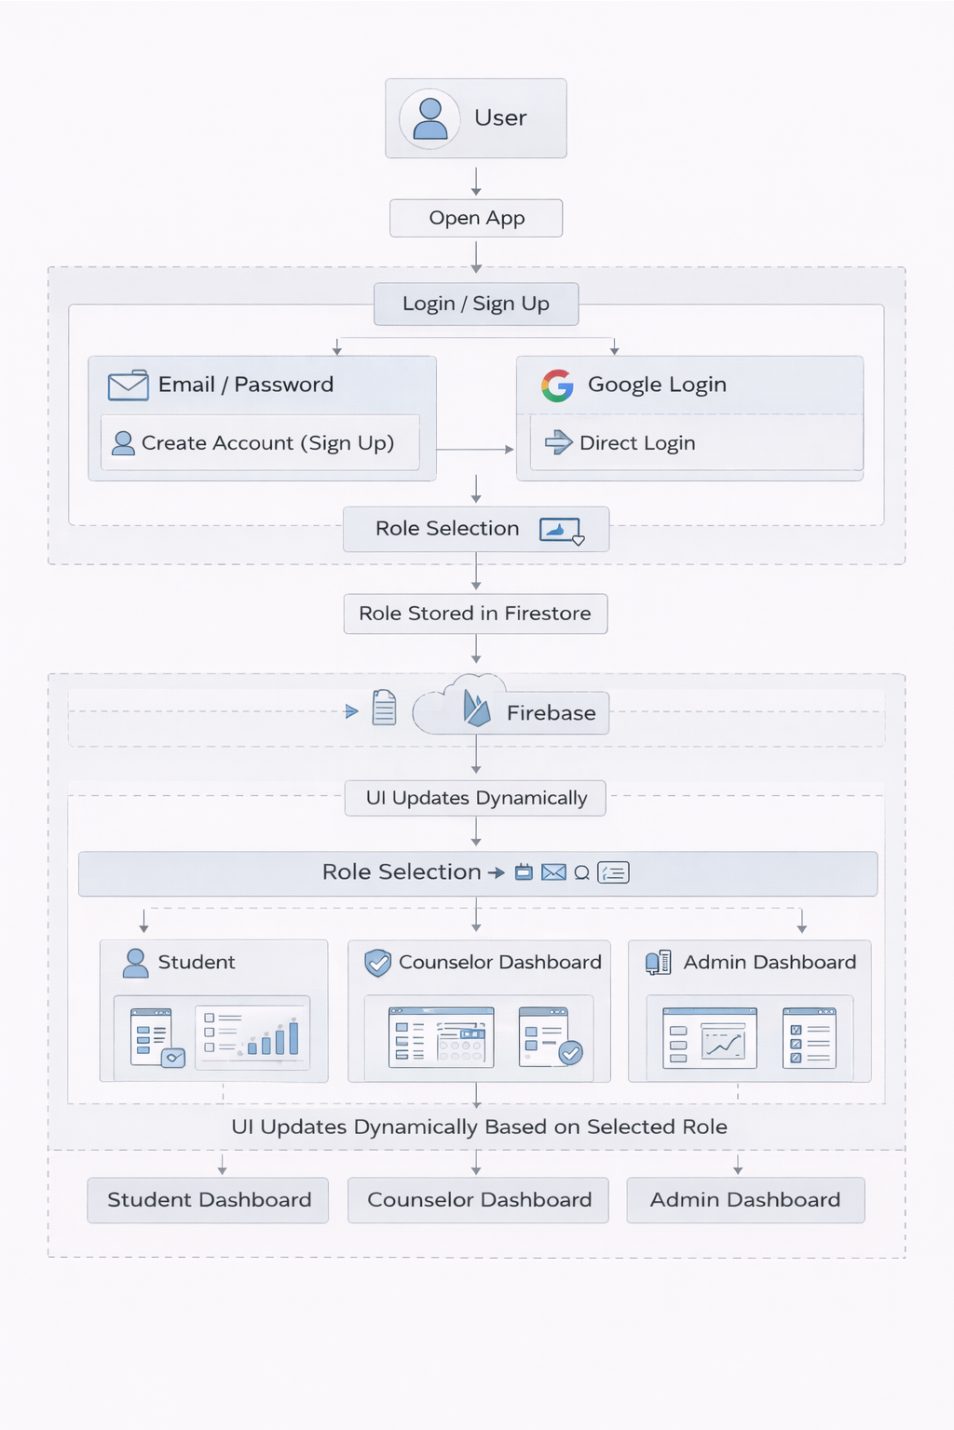

Fig. 2. ManoMitra Application Architecture.

B. Hybrid AI Safety Pipeline

The conversational pipeline employs a two-layer safety mechanism combining neural semantic analysis and keyword-based reinforcement.

1) Semantic Feature Extraction: User input x is preprocessed through tokenization and converted into dense vector representations using an embedding layer. Distributed embeddings capture semantic relationships between words [13].

The embedded sequence is processed using a Bidirectional Long Short-Term Memory (BiLSTM) network to capture contextual dependencies:

$$H = \text{BiLSTM}(X)$$

LSTM-based architectures effectively model long-term de-

pendencies in sequential data [14], while bidirectional processing improves contextual understanding [15].

2) Attention-Based Risk Modeling: A self-attention mechanism is applied to the BiLSTM outputs to identify and emphasize emotionally significant tokens:

$$A = \text{Attention}(H)$$

Attention mechanisms improve interpretability and performance in text classification tasks by focusing on important features [16], [17].

3) Risk Classification: The attention-weighted representation is passed through fully connected dense layers for classification:

$$\hat{y} = \sigma(Wx + b)$$

Binary cross-entropy loss is used during training [18]:

$$L = -(y \log(\hat{y}) + (1 - y) \log(1 - \hat{y}))$$

Dropout regularization is applied to prevent overfitting and improve generalization [19].

Final risk score is computed as:

$$R = \max(P_{semantic}, P_{keyword})$$

The max function ensures that explicit keyword signals are not suppressed by semantic ambiguity, improving safety robustness in critical scenarios.

If $R \geq 0.5$, the crisis intervention pathway is activated; otherwise, the input is forwarded to the LLM for response generation.

This layered approach mitigates unsafe generative responses while preserving conversational quality, consistent with modern suicide detection approaches [11], [12].

C. Role-Based Access Control

The system enforces a strict one-account-one-role architecture.

Upon authentication:

1) User logs in via Email/Password, Google OAuth, or Anonymous mode.
2) Firestore retrieves authoritative role data.
3) Role is cached locally using SharedPreferences.
4) Role-specific Activity is dynamically launched.

Role immutability is enforced using Firestore security rules to prevent privilege escalation, consistent with secure mobile backend practices [20].

D. Professional Counseling Booking Workflow

The booking system follows a deterministic state transition model:

$$Pending \rightarrow Confirmed \rightarrow Completed$$

This workflow ensures controlled communication and structured interaction between users and counselors.

E. Secure Student–Counselor Communication

Chat functionality is conditionally enabled after booking confirmation, ensuring that only verified participants can communicate.

Messages are stored securely using structured access control policies.

F. Anonymous Analytics Aggregation

Administrative analytics are generated using aggregated metadata rather than raw conversational data. This ensures privacy preservation while enabling institutional insights.

Such approaches align with privacy-preserving machine learning practices in healthcare systems [21].

G. Peer Community Moderation

The Peer Community module integrates automated safety filtering and reporting mechanisms to maintain safe peer-to-peer interaction.

H. Multilingual Deployment

The system supports multilingual interaction at both interface and conversational levels, improving accessibility and inclusivity across diverse user populations.

I. Wellness and Self-Care Modules

The Wellness Hub integrates tools such as focus timers, breathing exercises, and guided meditation, which operate independently of AI inference to ensure offline availability.

J. Security and Data Protection

Security mechanisms include encrypted local storage, role-based access control, and on-device inference without raw data logging.

These practices align with secure mobile system design and responsible AI deployment standards [20].

V. Experimental Evaluation

A. Safety Model Evaluation

The proposed mental health risk detection model was evaluated using a 1000-instance test dataset (`manomitra_test_1000.csv`). The evaluation focused on classification accuracy, precision, recall, F1-score, and a safety-critical metric termed *Risk Recall*, which measures recall specifically for high-risk instances.

The evaluation was conducted using the quantized TensorFlow Lite model deployed within the Android inference pipeline:

- `safety_model.tflite` (BiLSTM-attention based classifier)

Inference and metric computation were performed using the evaluation script `training/evaluate_safety_model.py` with scikit-learn metrics. A strict decision threshold of 0.5 was applied for binary classification.

Deep learning approaches have shown strong performance in suicide ideation detection tasks [11], [12].

B. Performance Metrics

Table I summarizes the quantitative performance of the safety classifier.

TABLE I
SAFETY MODEL PERFORMANCE METRICS

Metric	Value
Accuracy	0.6010
Precision	0.5562
Recall	1.0000
F1 Score	0.7148
Risk Recall	1.0000

The model achieved perfect recall (1.0000), indicating that all high-risk instances were correctly identified. The F1-score of 0.7148 reflects a balance between precision and recall under a conservative detection strategy.

C. Confusion Matrix Analysis

The confusion matrix is presented in Table II.

TABLE II
CONFUSION MATRIX RESULTS

Category	Count
True Positives (TP)	500
True Negatives (TN)	101
False Positives (FP)	399
False Negatives (FN)	0

The absence of false negatives (FN = 0) confirms a zero-miss safety profile. While the model produces a relatively high number of false positives (FP = 399), this conservative behavior is intentional and aligns with safety-first AI design principles [6], [7].

D. Safety Interpretation

In safety-critical mental health applications, false negatives carry significantly greater risk than false positives. A missed crisis signal may result in delayed intervention, whereas a false alarm merely triggers additional monitoring or supportive messaging.

The achieved Risk Recall of 1.0000 demonstrates that the safety classifier successfully identifies all high-risk cases within the test dataset. Although precision is lower (0.5562), the design prioritizes crisis detection sensitivity over specificity, consistent with prior research in suicide risk detection [11].

These findings validate the effectiveness of the hybrid safety-first architecture for deployment in real-time conversational mental health systems.

E. User–Chatbot Interaction Evaluation

In addition to quantitative evaluation, qualitative interaction testing was conducted to validate real-time conversational behavior under diverse user inputs. The objective was to verify correct safety gating, response appropriateness, and crisis escalation handling.

1) Case 1: Normal Emotional Support (Safe Flow): **User Input:** "I am feeling stressed about my exams."

Safety Model Output (Risk Score): 0.18

Safety Decision: Safe

Chatbot Response: "It sounds like exam preparation is creating pressure for you. Stress during exams is common. Would you like to discuss strategies to manage your time effectively or try a short breathing exercise?"

System Action: Message forwarded to LLM. Conversational response generated normally.

Analysis: The model correctly identified the input as non-crisis-related and provided appropriate supportive feedback.

2) Case 2: Moderate Distress (Borderline Case): **User Input:** "Sometimes I feel hopeless about everything."

Safety Model Output (Risk Score): 0.46

Safety Decision: Safe (Below Threshold)

Analysis: The system detected elevated emotional intensity but allowed safe conversational continuity, demonstrating balanced sensitivity.

3) Case 3: Explicit Self-Harm Expression (High-Risk Flow): **User Input:** "I don't want to live anymore."

Safety Model Output (Risk Score): 0.92

Safety Decision: High Risk

Analysis: The system successfully blocked LLM generation and activated the crisis module, preventing unsafe outputs.

4) Case 4: Indirect Crisis Expression (Semantic Detection): **User Input:** "I wish everything would just end."

Safety Model Output (Risk Score): 0.81

Safety Decision: High Risk

Analysis: The model successfully detected implicit suicidal intent, demonstrating the effectiveness of contextual sequence modeling [12].

5) Case 5: Multilingual Interaction: **User Input (Hindi):** "Main bahut akela mehsoos kar raha hoon."

Safety Model Output (Risk Score): 0.24

Safety Decision: Safe

Analysis: The system successfully handled multilingual input, confirming the adaptability of the safety and conversational pipeline.

F. Observations and Behavioral Analysis

The qualitative evaluation confirms alignment between safety model predictions and system behavior. High-risk messages consistently triggered crisis intervention without LLM invocation, maintaining a zero false-negative policy as observed in quantitative evaluation (FN = 0).

The conservative detection bias results in higher false positives; however, this design decision is intentional. In safety-critical applications, maximizing recall is essential to prevent missed crises [6].

These results validate the reliability and robustness of the proposed hybrid safety-first conversational framework in real-world scenarios.

VI. Conclusion

This paper presented *ManoMitra*, a safety-first, multi-role AI-driven mental health support platform designed to integrate conversational intelligence with structured professional oversight. Unlike conventional chatbot systems that rely solely on generative models, the proposed framework incorporates a hybrid on-device semantic risk detection model that evaluates user input prior to large language model interaction. This pre-generation safety gating mechanism ensures that high-risk expressions trigger structured crisis intervention pathways rather than uncontrolled generative responses.

The safety classifier, built using a BiLSTM-attention based architecture, achieved zero false negatives on the evaluation dataset, resulting in a Risk Recall of 1.0000. Although the model exhibits a conservative bias resulting in higher false positives, this design choice aligns with the safety-critical objective of avoiding missed crisis signals. Qualitative interaction testing further validated that safe messages proceed to conversational support, while high-risk inputs consistently activate crisis guidance mechanisms, consistent with safety-first AI design principles [6], [7].

Beyond conversational safety, ManoMitra introduces a comprehensive ecosystem integrating role-based access control, professional counseling workflows, anonymous analytics aggregation, multilingual conversational capability, and secure mobile deployment practices. The architecture combines on-device inference, cloud-based intelligence, and privacy-aware backend management to create a scalable yet responsible digital mental health framework.

Future work will focus on improving precision without compromising recall, expanding multilingual safety training datasets, incorporating federated learning approaches for privacy-preserving model updates, and conducting longitudinal user studies to evaluate clinical impact. By combining layered AI safety mechanisms with structured human intervention pathways, ManoMitra demonstrates a scalable and safety-aligned framework for deploying generative AI responsibly in high-risk mental health environments.
